

Probabilistic Graphical Models

Approximate Inference: Monte Carlo
and Sequential Monte Carlo methods

Eric Xing

Lecture 13, February 27, 2019

Reading: see class homepage

Approaches to inference

- ❑ Exact inference algorithms
 - ❑ The elimination algorithm
 - ❑ Message-passing algorithm (sum-product, belief propagation)
 - ❑ The junction tree algorithms
- ❑ Approximate inference techniques
 - ❑ Variational algorithms
 - ❑ Loopy belief propagation
 - ❑ Mean field approximation
 - ❑ Stochastic simulation / sampling methods
 - ❑ Markov chain Monte Carlo methods

How to represent a joint, or a marginal distribution?

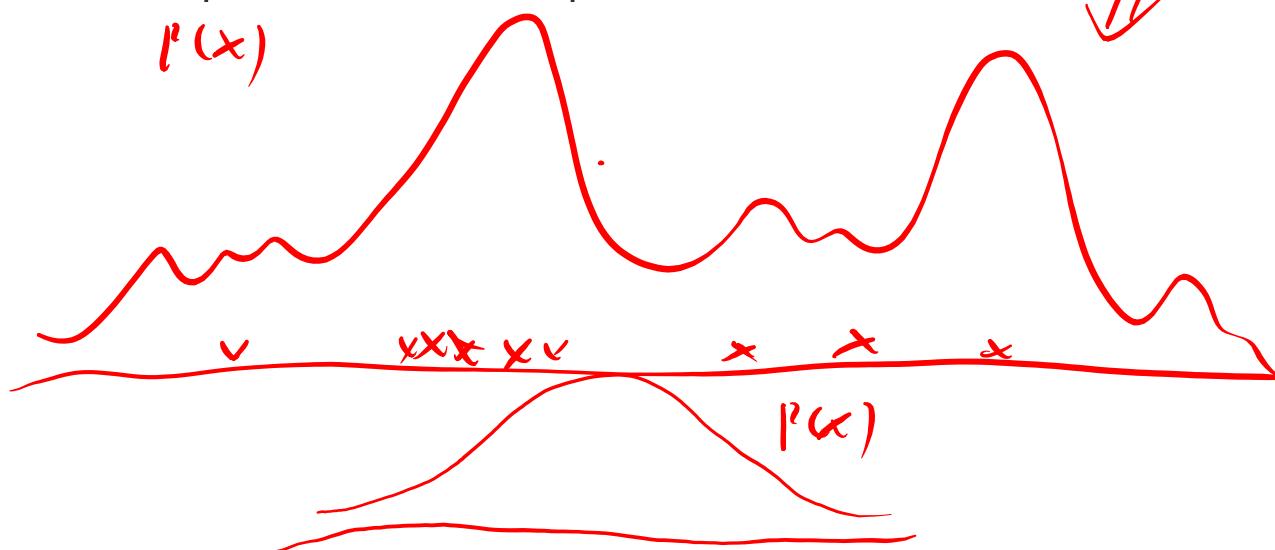

- Closed-form representation

- E.g.,

$$(x_1, \dots, x_p)^T \sim \frac{1}{(2\pi)^{p/2} |\Sigma|^{1/2}} \exp \left(-\frac{1}{2} (x - \mu)^T \Sigma^{-1} (x - \mu) \right)$$

$\cancel{P(x)}$
 $\cancel{A(x)}$

- Sample-based representation:

$$\underbrace{E_p(f(x)) = \int f(x)p(x)dx}_{\text{closed-form}}$$

$$x^{(n)} \sim p(x)$$

$$n=1 \dots N$$

$$E_p(f(x)) = \frac{\sum f(x^n)}{N}$$

$$\{x^{(1)}, \dots, x^{(N)}\}$$

Monte Carlo methods

- Draw random samples from the desired distribution
- Yield a stochastic representation of a complex distribution
 - marginals and other expectations can be approximated using sample-based averages

$$E[f(x)] = \frac{1}{N} \sum_{t=1}^N f(x^{(t)})$$

- Asymptotically exact and easy to apply to arbitrary models
- Challenges:
 - how to draw samples from a given dist. (not all distributions can be trivially sampled)?
 - how to make better use of the samples (not all sample are useful, or equally useful, see an example later)?
 - how to know we've sampled enough?

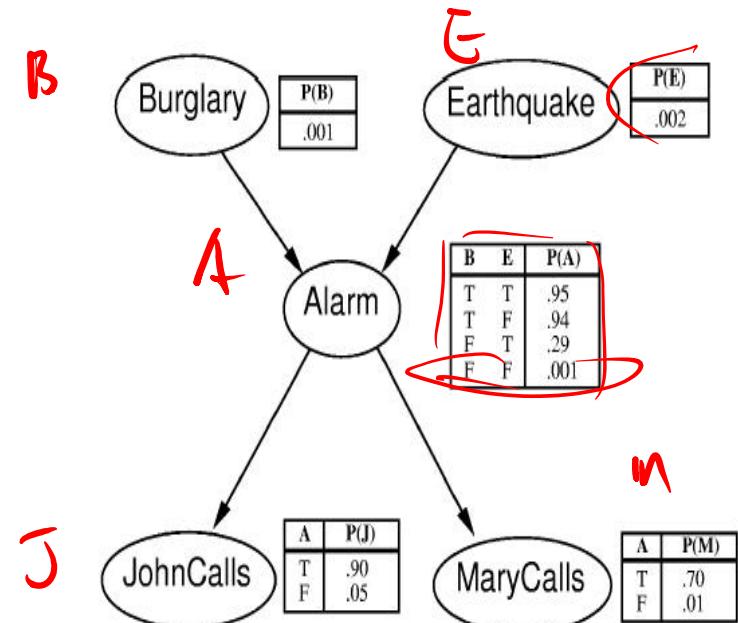

Example: naive sampling

$$P(X_1, \dots, X_m) = \frac{P(B)P(\bar{E})}{P(A|B, \bar{E})} \dots$$

$$\underline{X}^{(m)} = \begin{bmatrix} X_1 \\ \vdots \\ X_m \end{bmatrix} \sim P_X$$

- Construct samples according to probabilities given in a BN.

Alarm example: (Choose the right sampling sequence)

- Sampling: $P(B) = <0.001, 0.999>$ suppose it is false, B0. Same for E0. $P(A|B0, E0) = <0.001, 0.999>$ suppose it is false...
- Frequency counting: In the samples right, $P(J|A0) = P(J, A0) / P(A0) = <1/9, 8/9>$.

E0	B0	A0	M0	J0

Example: naive sampling

- Construct samples according to probabilities given in a BN.

Alarm example: (Choose the right sampling sequence)

3) what if we want to compute $P(J|A1)$?

~~we have only one sample ...~~

$\text{P}(J|A1)=\text{P}(J,A1)/\text{P}(A1)=<0, 1>$.

4) what if we want to compute $P(J|B1)$?

~~No such sample available!~~

$\text{P}(J|A1)=\text{P}(J,B1)/\text{P}(B1)$ can not be defined.

For a model with hundreds or more variables, rare events will be very hard to garner enough samples even after a long time or sampling ...

Monte Carlo methods (cond.)

- ❑ Direct Sampling
 - ❑ We have seen it.
 - ❑ Very difficult to populate a high-dimensional state space
- ❑ Rejection Sampling
 - ❑ Create samples like direct sampling, only count samples which is consistent with given evidences.
- ❑ Likelihood weighting, ...
 - ❑ Sample variables and calculate evidence weight. Only create the samples which support the evidences.
- ❑ Markov chain Monte Carlo (MCMC)
 - ❑ Metropolis-Hastings
 - ❑ Gibbs

Rejection sampling

- Suppose we wish to sample from dist. $\Pi(X) = \Pi'(X)/Z$
- $\Pi(X)$ is difficult to sample, but $\Pi'(X)$ is easy to evaluate
- Sample from a simpler dist $Q(X)$
- Rejection sampling

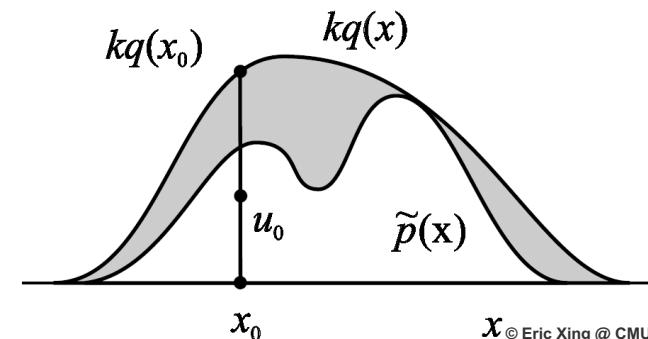

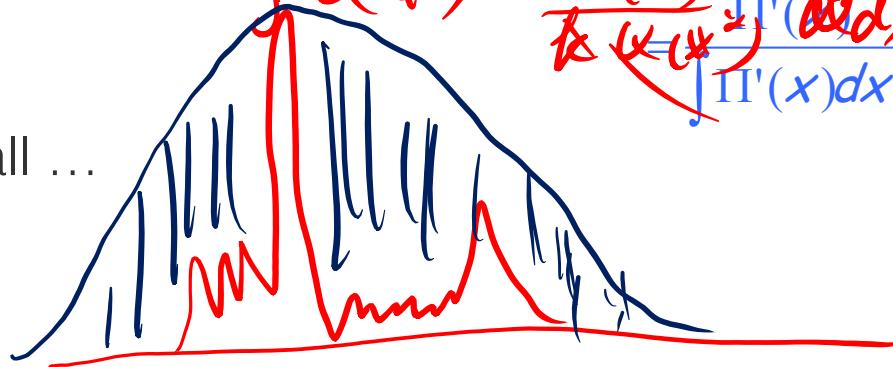

$$x^* \sim Q(X),$$

accept x^* w.p. $\Pi'(x^*)/kQ(x^*)$ $\Rightarrow x^* \sim \pi(x)$

- Correctness:

$$\begin{aligned} P(x^*) &= \frac{\alpha(x^*) \cdot \Pi'(x^*)}{\alpha(x^*) \cdot \Pi'(x^*) + \int_{\Pi'(x^*)}^{\Pi(x^*)} \Pi'(x) dx} \\ &= \frac{\Pi'(x^*)}{\int_{\Pi'(x^*)}^{\Pi(x^*)} \Pi'(x) dx} = \frac{\Pi'(x^*)}{\int_{\Pi'(x^*)}^{\Pi(x^*)} \Pi'(x) dx} = \Pi(x^*) \end{aligned}$$

- Pitfall ...

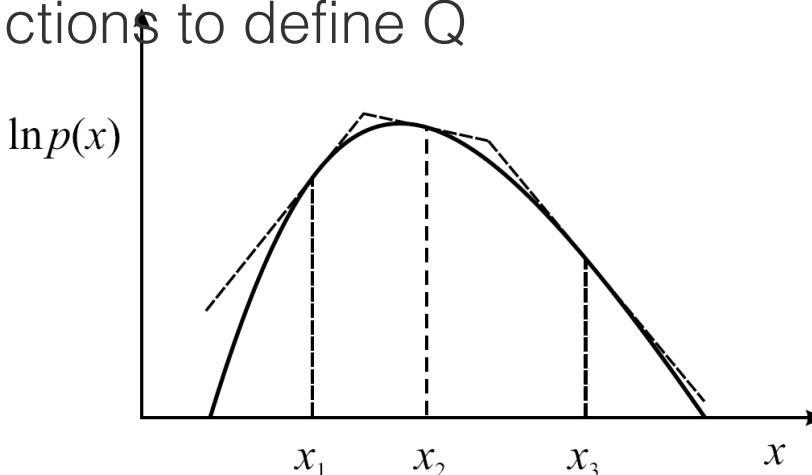

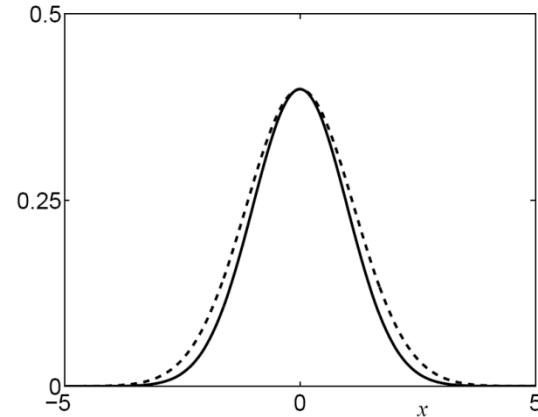

Rejection sampling

$$P = \frac{1}{\sigma_q^d \exp}$$

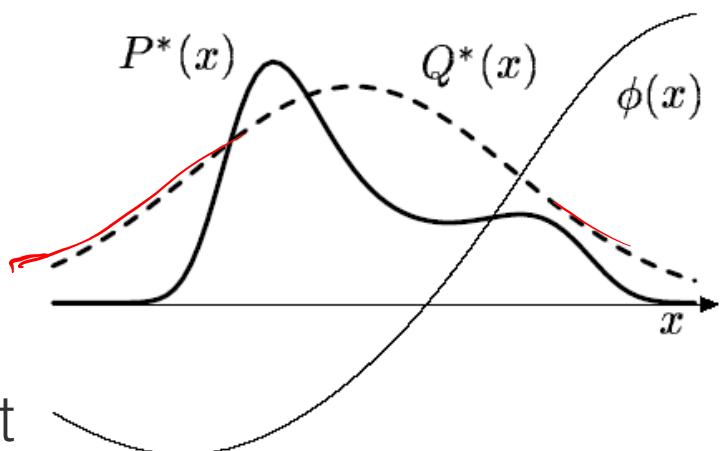

- Pitfall:
 - Using $Q = \mathcal{N}(\mu, \sigma_q^{2/d})$ to sample $P = \mathcal{N}(\mu, \sigma_p^{2/d})$
 - If σ_q exceeds σ_p by 1%, and dimensional=1000,
 - The optimal acceptance rate $k = (\sigma_q/\sigma_p)^d \approx 1/20,000$
 - Big waste of samples!
- Adaptive rejection sampling
 - Using envelope functions to define Q

Unnormalized importance sampling

- Suppose sampling from $P(\cdot)$ is hard.
- Suppose we can sample from a "simpler" proposal distribution $Q(\cdot)$ instead.
- If Q dominates P (i.e., $Q(x) > 0$ whenever $P(x) > 0$), we can sample from Q and reweight:

- What

$$\begin{aligned}\langle f(X) \rangle &= \int f(x)P(x)dx \\ &= \int f(x) \frac{P(x)}{Q(x)} \frac{Q(x)}{Q(x)} dx \\ &\approx \frac{1}{M} \sum_m f(x^m) \frac{P(x^m)}{Q(x^m)} \\ &= \frac{1}{M} \sum_m f(x^m) w^m\end{aligned}$$

where $x^m \sim Q(X)$

$$x^m \sim Q(x)$$
$$w^m = \frac{P(x^m)}{Q(x^m)}$$

$\{x^m\}$ $w^m \}$ M

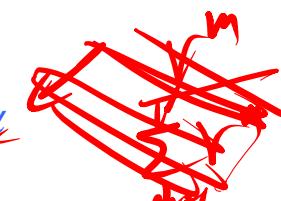

Normalized importance sampling

- Suppose we can only evaluate $P'(x) = \alpha P(x)$ (e.g. for an MRF).
- We can get around the nasty normalization constant α as follows:

$$\text{Let } r(X) = \frac{P'(X)}{Q(X)}$$

$$\Rightarrow \langle r(X) \rangle_Q = \int \frac{P'(X)}{Q(X)} Q(X) dx = \int P'(X) dx = \alpha$$

- Now

$$\begin{aligned}\langle f(X) \rangle_P &= \int f(x) P(x) dx = \frac{1}{\alpha} \int f(x) \frac{P'(x)}{Q(x)} Q(x) dx \\ &= \int f(x) r(x) Q(x) dx \\ &\approx \sum_m f(x^m) r^m \quad \text{where } x^m \sim Q(X) \\ &= \sum_m f(x^m) w^m \quad \text{where } w^m = \frac{r^m}{\sum_m r^m}\end{aligned}$$

$$\left\{ x^m, w^m = \frac{r^m}{\sum_m r^m} \right\}$$

$x^m \sim Q(x)$
 $w^m = \frac{r^m}{\sum_m r^m}$

Normalized vs unnormalized importance sampling

- Unnormalized importance sampling is unbiased:

$$E_Q[f(X)w(X)] = \mathbb{E}_{P^*}(f)$$

- Normalized importance sampling is biased, e.g., for $M = 1$:

$$E_Q\left[\frac{f(x^1)r(x^1)}{r(x^1)}\right] = \cancel{\mathbb{E}_P(f)}$$

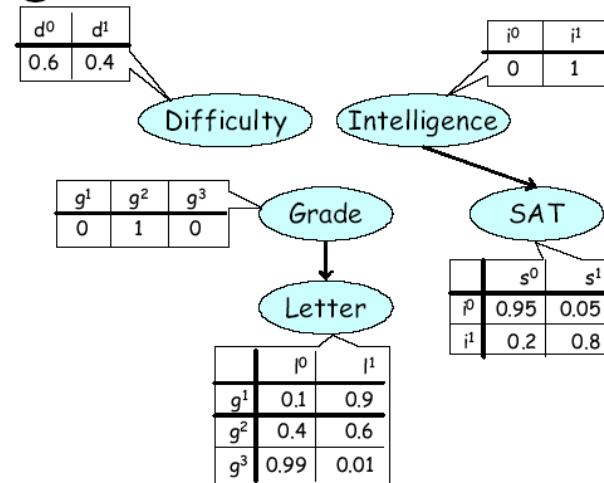

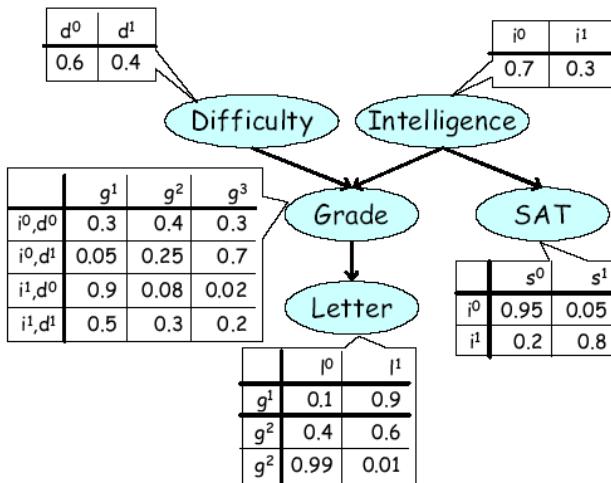

- However, the **variance** of the normalized importance sampler is usually lower in practice.
- Also, it is common that we can evaluate $P'(x)$ but not $P(x)$, e.g. $P(x|e) = P'(x, e)/P(e)$ for Bayes net, or $P(x) = P'(x)/Z$ for MRF.

Likelihood weighting

- We now apply normalized importance sampling to a Bayes net.
- The proposal Q is gotten from the mutilated BN where we **clamp evidence nodes**, and cut their incoming arcs. Call this P_M .

- The unnormalized weight is $w_m = P'(x^m, e) / P_M(x^m)$
- So for $f(X_i) = \delta(X_i = x_i)$, we get where

$$w_m = P'(x^m, e) / P_M(x^m)$$

$$\hat{P}(X_i = x_i | e) = \frac{\sum_m w_m \delta(x_i^m = x_i)}{\sum_m w_m}$$

Likelihood weighting algorithm

$[x_{1:n}, w] = \text{function LW(CPDs, } G, E)$

let X_1, \dots, X_n be a topological ordering of G

$w = 1$

$x = (0, \dots, 0)$

for $i = 1 : n$

 let $u_i = x(Pa_i)$

 if $X_i \notin E$

 then sample x_i from $P(X_i|u_i)$

 else

$x_i = e(X_i)$

$w = w * P(x_i|u_i)$

Efficiency of likelihood weighting

- The efficiency of importance sampling depends on how close the proposal Q is to the target P.
- Suppose all the evidence is at the roots. Then $Q = P(X|e)$, and all samples have weight 1.
- Suppose all the evidence is at the leaves. Then Q is the prior, so many samples might get small weight if the evidence is unlikely.
- We can use arc reversal to make some of the evidence nodes be roots instead of leaves, but the resulting network can be much more densely connected.

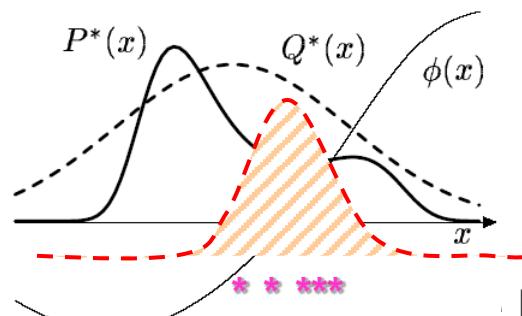

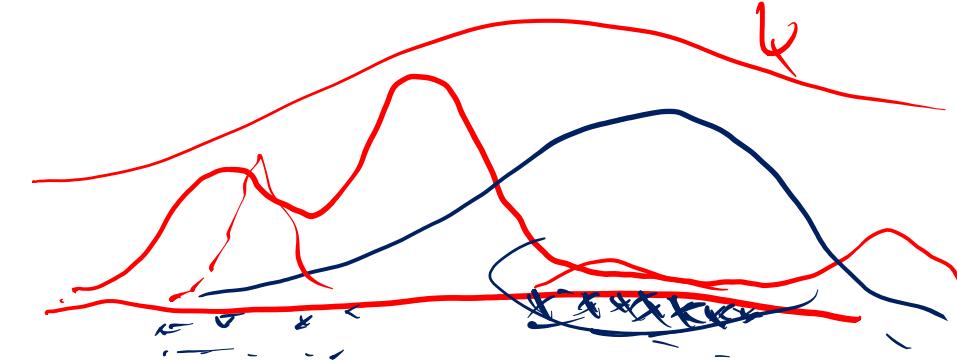

Weighted resampling

$$w = \frac{p}{q}$$

- Problem of importance sampling: depends on how well Q matches P
 - If $P(x)f(x)$ is strongly varying and has a significant proportion of its mass concentrated in a small region, r_m will be dominated by a few samples

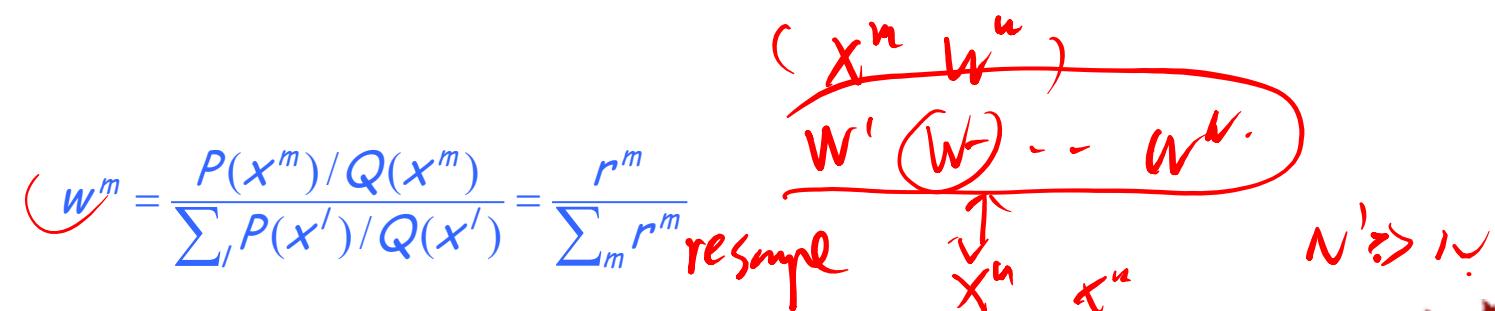

Note that if the high-prob mass variance of P and potentially erroneous.

low-prob mass region of P , the can be small even if the samples come from low-prob region of

- $r^m = P(x^m)/Q(x^m)$
- Solution
 - Use heavy tail Q .
 - Weighted resampling

$$w^m = \frac{P(x^m)/Q(x^m)}{\sum_i P(x^i)/Q(x^i)} = \frac{r^m}{\sum_m r^m}$$

Weighted resampling

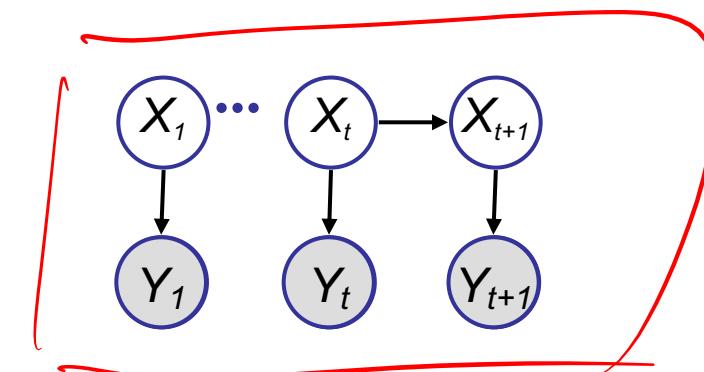

- Sampling importance resampling (SIR):

- Draw N samples from $Q(X_1 \dots X_N)$
- Constructing weights: $w_1 \dots w_N$,
- Sub-sample x from $\{X_1 \dots X_N\}$ w.p. $(w_1 \dots w_N)$

$$w^m = \frac{P(x^m)/Q(x^m)}{\sum_i P(x^i)/Q(x^i)} = \frac{r^m}{\sum_m r^m}$$

- Particular Filtering

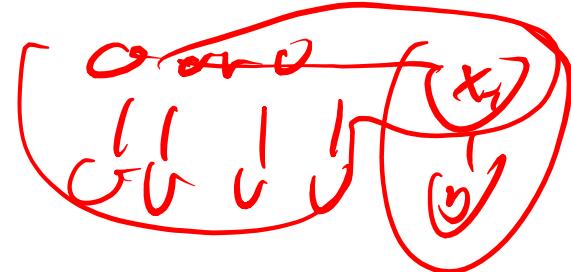

- A special weighted resampler
- Yield samples from posterior $p(X_t|Y_{1:t})$
- Also known as sequential Monte Carlo

Sketch of Particle Filters

$$p(X_{t+1} | Y_{1:t+1})$$

- The starting point

$$p(X_t | Y_{1:t}) = p(X_t | Y_t, Y_{1:t-1})$$
- Thus $p(X_t | Y_{1:t})$ is represented by

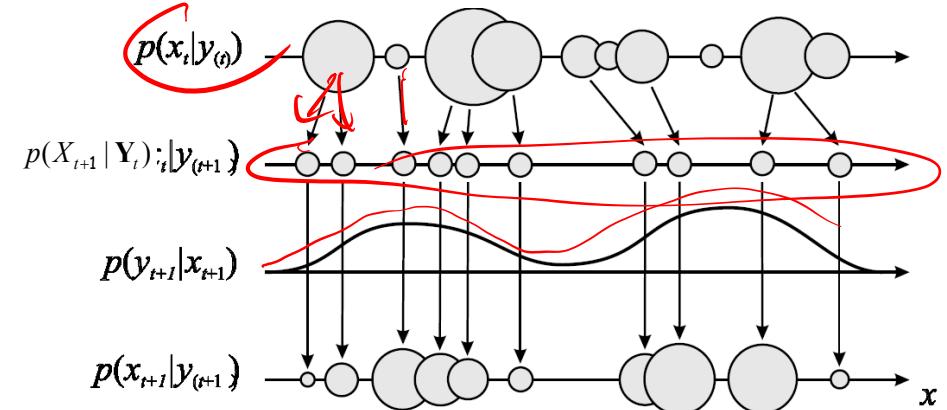

$$\left\{ X_t^m \sim p(X_t | Y_{1:t-1}), w_t^m = \frac{p(Y_t | X_t^m)}{\sum_{m=1}^M p(Y_t | X_t^m)} \right.$$
- A sequential weighted resampler
 - Time update

$$p(X_{t+1} | Y_{1:t}) = \int p(X_{t+1} | X_t) p(X_t | Y_{1:t}) dX_t$$

$$= \sum_m w_t^m p(X_{t+1} | X_t^{(m)}) \quad (\text{sample from a mixture model})$$
 - Measurement update

$$p(X_{t+1} | Y_{1:t+1}) = \int p(X_{t+1} | Y_{1:t}) p(Y_{t+1} | X_{t+1}) dX_{t+1}$$

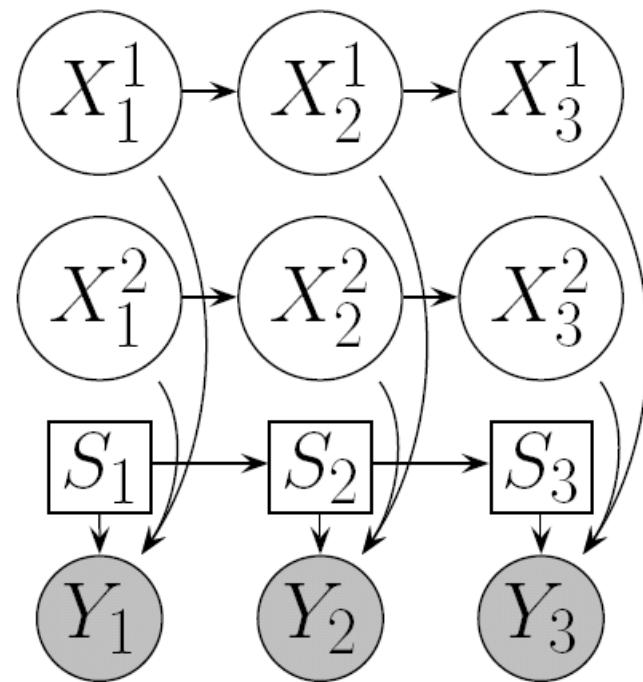

$$\Rightarrow \left\{ X_{t+1}^m \sim p(X_{t+1} | Y_{1:t}), w_{t+1}^m = \frac{p(Y_{t+1} | X_{t+1}^m)}{\sum_{m=1}^M p(Y_{t+1} | X_{t+1}^m)} \right\} \quad (\text{reweight})$$

PF for switching SSM

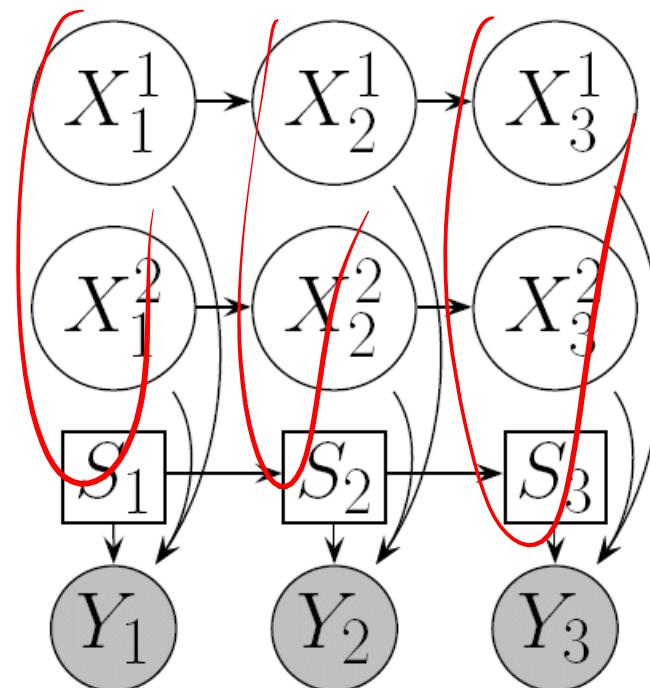

- Recall that the belief state has $O(2^t)$ Gaussian modes

PF for switching SSM

- ❑ Key idea: if you knew the discrete states, you can apply the right Kalman filter at each time step.
- ❑ So for each old particle m , sample $S_t^m \sim P(S_t | S_{t-1}^m)$ from the prior, apply the KF (using parameters for S_t^m) to the old belief state $(\hat{x}_{t-1|t-1}^m, P_{t-1|t-1}^m)$ to get an approximation to $P(X_t | y_{1:t}, s_{1:t}^m)$
- ❑ Useful for online tracking, fault diagnosis, etc.

Rao-Blackwellised sampling

- Sampling in high dimensional spaces causes high variance in the estimate.
- RB idea: sample some variables X_p , and conditional on that, compute expected value of rest X_d analytically:

$$\begin{aligned} E_{p(X|e)}[f(X)] &= \int p(x_p, x_d | e) f(x_p, x_d) dx_p dx_d \\ &= \int_{x_p} p(x_p | e) \left(\int_{x_d} p(x_d | x_p, e) f(x_p, x_d) dx_d \right) dx_p \\ &= \int_{x_p} p(x_p | e) E_{p(X_d|x_p,e)}[f(x_p, X_d)] dx_p \\ &= \frac{1}{M} \sum_m E_{p(X_d|x_p^m,e)}[f(x_p^m, X_d)], \quad x_p^m \sim p(x_p | e) \end{aligned}$$

- This has lower variance, because of the identity:

$$\text{var}[\tau(X_p, X_d)] = \text{var}[E[\tau(X_p, X_d) | X_p]] + E[\text{var}[\tau(X_p, X_d) | X_p]]$$

Rao-Blackwellised sampling

- Sampling in high dimensional spaces causes high variance in the estimate.
- RB idea: sample some variables X_p , and conditional on that, compute expected value of rest X_d analytically:

$$\begin{aligned} E_{p(X|e)}[f(X)] &= \int p(x_p, x_d | e) f(x_p, x_d) dx_p dx_d \\ &= \int p(x_p | e) \left(\int_{x_d} p(x_d | x_p, e) f(x_p, x_d) dx_d \right) dx_p \\ &= \int_{x_p} p(x_p | e) E_{p(X_d|x_p,e)}[f(x_p, X_d)] dx_p \\ &= \frac{1}{M} \sum_m E_{p(X_d|x_p^m,e)}[f(x_p^m, X_d)] \quad x_p^m \sim p(x_p | e) \end{aligned}$$

- This has lower variance, because of the identity:
$$\text{var}[\tau(X_p, X_d)] = \text{var}[E[\tau(X_p, X_d) | X_p]] + E[\text{var}[\tau(X_p, X_d) | X_p]]$$
is a lower variance estimator.
$$\text{var}[E[\tau(X_p, X_d) | X_p]] \leq \text{var}[\tau(X_p, X_d)] \quad \tau(X_p, X_d) = E[f(X_p, X_d) | X_p]$$
- Hence

Summary: Monte Carlo Methods

- ❑ Direct Sampling
 - ❑ Very difficult to populate a high-dimensional state space
- ❑ Rejection Sampling
 - ❑ Create samples like direct sampling, only count samples which is consistent with given evidences.
- ❑ Likelihood weighting, ...
 - ❑ Sample variables and calculate evidence weight. Only create the samples which support the evidences.
- ❑ Markov chain Monte Carlo (MCMC)
 - ❑ Metropolis-Hastings
 - ❑ Gibbs
